㉒ Seal.

㉓ The invention refers to a seal for bearing spaces, wall channels for shafts and the like where the seal is fitted to the shaft (1). The seal is characterized in that it incorporates a sheet metal strutting (3) projecting radially outwards, and on the side facing away from the space intended to be sealed off being equipped with mainly radially extending vanes (2), the radial extension of which mainly coincide with the radial extension of the sheet metal strutting (3).

SEAL

The present invention refers to sealings of the type intended for sealing off bearing spaces, wall channels for shafts and the like.

Seals of the above mentioned type are earlier known and exist in a very large number of embodiments. They usually are fitted to the non-mobile part and seals againsts the rotating shaft or some member fitted thereto, by means of one or more sealing lips which preferably consist of rubber. Seals fitted to the rotating shaft are also know. The common feature of all these seals is that the sealing lip shall be given a proper pressure against another part in the device and thus prevent dirt, water and the like from penetrating into the space intended to be sealed off. It is very important that the lip contacts with a suitable pressure. If this pressure becomes too high the friction will be too big and if it becomes too low, then the sealing function will be poor.

The space outside the seal sometimes can be very fouled, which puts big demands on the seal. In order to certain a satisfactory sealing effect it is sometime provided several seals, often of different types, such as lip seals combined with labyrinth seals. One purpose thereof is that such a low amount of dirt as possible shall come into contact with the final inner seal. Such an arrangement with several seals can be complex and thereby also expensive as well to manufacture as in assembly.

In order to, in a simple manner, solve the problem of sealing off against heavily fouled surroundings, without the use of combinations, the invention proposes a seal for bearing spaces, wall channels for shafts and the like, whereby the seal is fitted to a shaft intended for rotation, and which is characterized thereby that it incorporates a sheet metal strutting projecting radially outwards, and, on the side facing away from the space intended to be sealed off, being equipped with mainly radially extending vanes, the radial

2

extension of which mainly coincide with the radial extension of the sheet metal strutting.

According to the invention the vanes in the seal should be made from rubber and be bonded to a sheet metal strutting in the seal.

It is also eligible that the sheet metal strutting in the seal is bent axially outwards in the vicinity of the shaft and that the vanes emanate from this bend.

On the side of the seal facing the space intended to be sealed off, the seal according to the invention should be provided with one ore more sealing lips of rubber.

The invention hereinafter will be further described with reference to the drawings, where figure 1 shows a section through a seal according to the invention fitted to a shaft and figure 2 shows the same seal when seen from the side and from the outside.

Figure 1 shows a shaft 1, on which is fitted a seal according to the invention incorporating radial vanes 2, which are bonded to a sheet metal strutting. Such as shown this sheet metal strutting 3 is provided with a bend 4 near the shaft 1. The vanes 2 emanate from this bend 4, which also will give strength to the vanes 2. The bend 4 also acts as mounting surface for the seal. On the inner side of the sheet metal strutting 3 there is a sealing lip 5, which in the present case contacts against a sheet metal member 6 and seals off against this. The sheet metal member 6 is fittedly mounted in a wall 7 or the like and is consequently non-rotating.

In figure 2 is shown the outer side of the seal, and this figure clearly shows the vanes 2. The number of such vanes is variable. A proper number is a 8 vanes.

The purpose of the vanes 2 according to the invention is to improve the fling-off effect of the seal so that particles.

3

liquid droplets or other dirt on the outside of the seal shall be thrown out and thus not come into the vicinity of the sealing lip 5. Beside the dirt thereby being removed it is also obtained an increased cooling effect in that turbulence will be created in the surrounding media.

The seal according to the invention presents a simplified improvement of earlier known seals, and the additional cost for the improvement is in the embodiment shown only a cost of the material in the vanes 2.

The invention is not limited to the embodiments mentioned above but can be varied in different manners within the scope of the claims.

0260441

CLAIMS

1. A seal for bearing spaces, wall channels for shafts and the like, whereby the seal is fitted to a shaft (1) intended for rotation,

characterized therein,
that it incorporates a sheet metal strutting (3) projecting radially outwards, and on the side facing away from the space intended to be sealed off being equipped with mainly radially extending vanes (2), the radial extension of which mainly coincide with the radial extension of the sheet metal strutting (3).

2. A seal as claimed in claim 1,

characterized therein,
that the vanes (2) are made from rubber and are bonded to the sheet metal strutting (3).

3. A seal as claimed in claim 1 or 2,

characterized therein,
that the sheet metal strutting (3) is bent axially in the vicinity of the shaft (1) and that the vanes (2) emanate from this bend (4).

4. A seal as claimed in claims 1 - 3,

characterized therein,
that it is provided with one or more rubber sealing lips (5) on the side facing the space intended to be sealed off.
